## Overview

jDeploy 5.1 introduces two major features that significantly improve the deployment and maintenance experience for Java desktop applications. Platform-specific bundle support allows developers to create optimized distributions that exclude unnecessary platform-specific files, dramatically reducing download sizes. Additionally, automatic version cleanup ensures that user systems remain clean by removing outdated application versions during updates.

## What's New in 5.1

### Platform-Specific Bundles

jDeploy 5.1 introduces a powerful new feature that allows you to create optimized bundles for each target platform by excluding unnecessary platform-specific files. This is particularly valuable for applications that include platform-specific native libraries or resources.

### The Problem It Solves

Modern Java applications, especially those using frameworks like Compose Multiplatform or including native libraries, often bundle platform-specific files for all supported platforms in a single distribution. This results in:

- **Unnecessarily large downloads** - Users download files for platforms they'll never use
- **Increased bandwidth costs** - Both for developers hosting downloads and users downloading them

- **Slower installation times** - Larger bundles take longer to download and extract

## Real-World Impact

The impact can be dramatic. For example:

- **Compose Multiplatform apps:** The People in Space demo drops from 100 MB to 40 MB per platform
- **jDeploy installer itself:** Reduced from ~35 MB to ~4 MB using this feature
- **Applications with native libraries:** Can see 50-70% size reductions per platform

## How It Works

Platform-specific bundles allow you to define which files should be included or excluded for each platform using a familiar `.gitignore`-style syntax. You can:

- **Exclude entire packages** - Remove Windows-specific code from Mac bundles
- **Use wildcards** - Match patterns like `.dll or-win64.so`
- **Override with keep patterns** - Exclude a package but keep specific sub-packages
- **Apply global rules** - Set exclusions that apply to all platforms

## Configuration Methods

Platform-specific bundles can be configured through multiple approaches:

### GUI Configuration

The new "Platform-Specific Bundles" tab in the project editor provides an intuitive interface with sub-tabs for each platform.

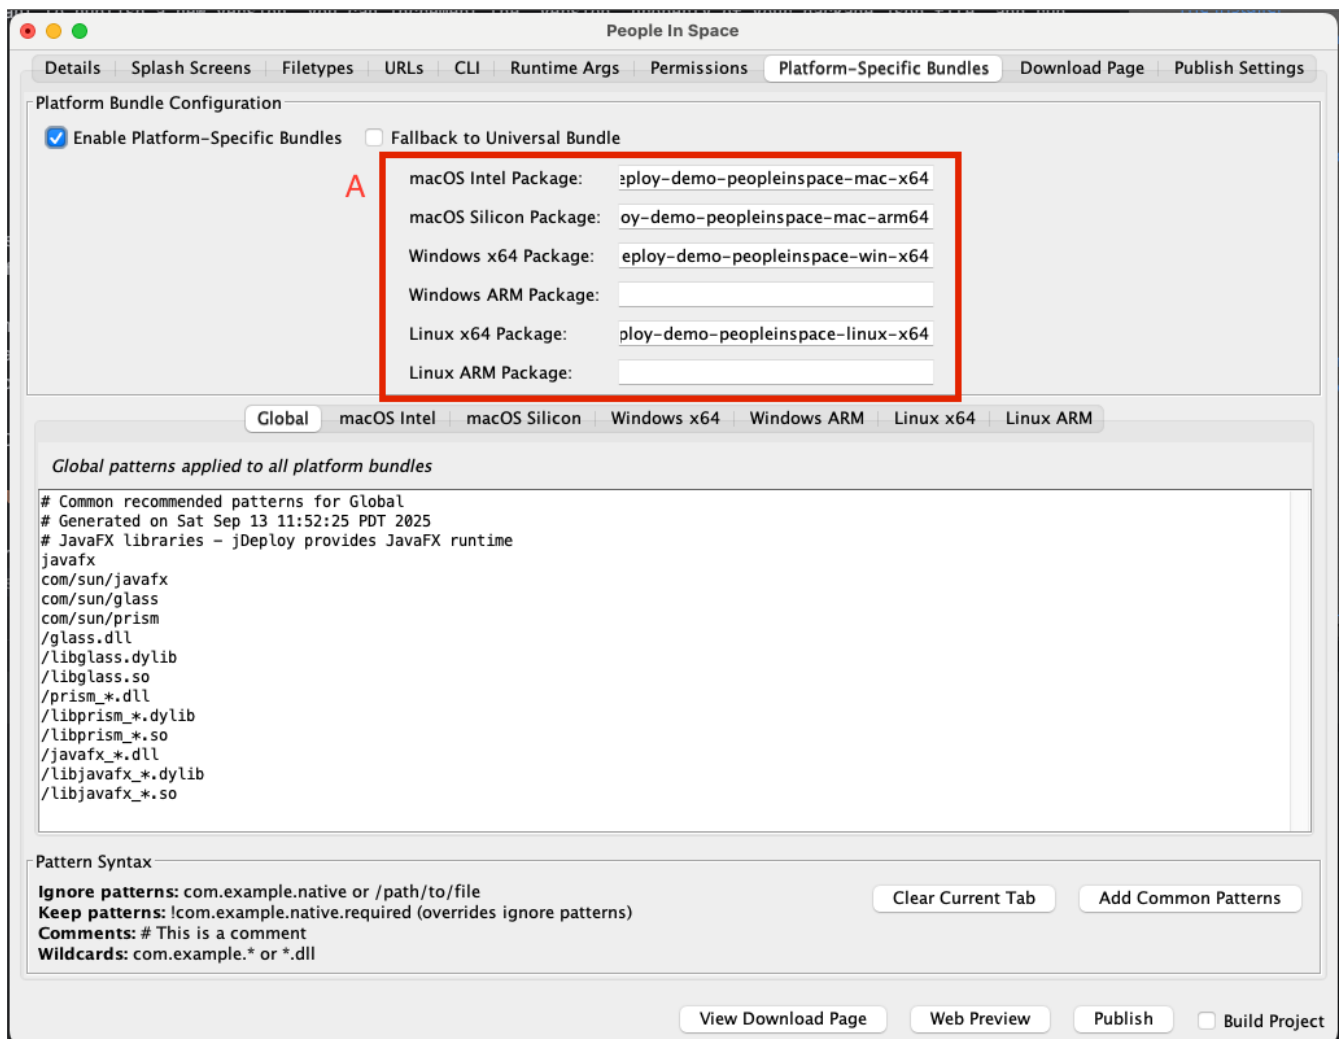

Figure 1. The Platform-Specific Bundles tab in the project editor

## Configuration Files

`.jdpignore` files use the same syntax as `.gitignore`:

- `.jdpignore` - Global patterns for all platforms
- `.jdpignore.mac-x64` - Mac Intel specific patterns
- `.jdpignore.mac-arm64` - Mac Apple Silicon specific patterns
- `.jdpignore.win-x64` - Windows x64 specific patterns
- `.jdpignore.win-arm64` - Windows ARM64 specific patterns
- `.jdpignore.linux-x64` - Linux x64 specific patterns
- `.jdpignore.linux-arm64` - Linux ARM64 specific patterns

## Package.json Configuration

Enable and configure platform-specific bundles in your `package.json`:

```
{
  "platformBundlesEnabled": true,
  "fallbackToUniversal": false,
  "packageMacX64": "my-app-macos-intel",
  "packageMacArm64": "my-app-macos-silicon",
}
```

```
"packageWinX64": "my-app-windows-x64",  
"packageWinArm64": "my-app-windows-arm64",  
"packageLinuxX64": "my-app-linux-x64",  
"packageLinuxArm64": "my-app-linux-arm64"  
}
```

## Pattern Examples

Here are some common patterns you might use:

### Exclude Windows DLLs from Mac/Linux bundles:

```
# In .jdpignore.mac-x64, .jdpignore.mac-arm64, .jdpignore.linux-*  
*.dll  
/native/windows  
com.myapp.windows
```

### Exclude all native libraries except for current platform:

```
# In .jdpignore.mac-arm64  
/native/*  
!/native/macos-arm64
```

### Remove platform-specific JNI libraries:

```
# In .jdpignore.win-x64  
*-darwin.dylib  
*-linux.so  
*-arm64.dll
```

## Automatic Version Cleanup (5.1.1)

Starting with jDeploy 5.1.1, the installer now automatically removes old application versions when installing updates. This addresses a long-standing issue where multiple versions could accumulate on user systems, consuming unnecessary disk space.

### Why This Matters

Previously, each application update would install alongside existing versions, leading to:

- **Disk space issues** - Multiple versions consuming gigabytes of space
- **User confusion** - Uncertainty about which version to use
- **System clutter** - Accumulated files in application directories

## How It Works

The automatic cleanup process:

1. **During Updates:** When installing a new version, the installer identifies and removes previous versions
2. **Preserves User Data:** Only application bundles are removed; user preferences and data remain intact
3. **Clean Uninstall:** Ensures proper cleanup through the system's uninstall mechanisms

## Configuration

This feature is enabled by default in 5.1.1. If you need to preserve old versions for specific use cases, you can disable it:

```
{
  "jdeploy": {
    "pruneOldVersions": false
  }
}
```

### NOTE

Before 5.1.1, old versions were never deleted. Starting with 5.1.1, the default behavior is to delete old versions (`pruneOldVersions: true`).

# Technical Improvements

## Bundle Generation Efficiency

The platform-specific bundle system introduces several technical improvements:

- **Parallel bundle generation** - Different platform bundles can be built simultaneously
- **Incremental filtering** - Only changed patterns trigger bundle regeneration
- **Smart caching** - Common files are cached between platform builds

## NPM Publishing Strategy

When using platform-specific bundles with npm:

- **Separate packages per platform** - Each platform publishes to its own npm package
- **Automatic fallback mechanism** - Can fall back to universal bundle if platform-specific isn't available
- **Version synchronization** - All platform packages maintain version parity

# File System Management

The version cleanup feature implements:

- **Safe deletion** - Verifies file ownership before removal
- **Atomic operations** - Either completes fully or rolls back
- **Cross-platform compatibility** - Works correctly on Windows, macOS, and Linux

## Migration Guide

### Upgrading from 5.0

jDeploy 5.1 is fully backward compatible with 5.0. Existing applications continue to work without any changes. To take advantage of new features:

#### Enabling Platform-Specific Bundles

1. **Open your project** in the jDeploy GUI
2. **Navigate to the "Platform-Specific Bundles" tab**
3. **Enable platform-specific bundles** by checking the checkbox
4. **Configure NPM package names** for each platform (if using npm)
5. **Add exclusion patterns** for each platform
6. **Test locally** using `jdeploy package`
7. **Publish** your optimized bundles

#### Configuring Version Cleanup

For applications updated to 5.1.1, automatic cleanup is enabled by default. No action is required unless you want to disable it:

```
{
  "jdeploy": {
    "pruneOldVersions": false // Only add this if you want to keep old versions
  }
}
```

## Best Practices

### Platform-Specific Bundle Patterns

#### Start with aggressive exclusions

Begin by excluding everything platform-specific, then add back what's needed:

```
# Exclude all native libraries
/native/*
# Keep only what this platform needs
!/native/current-platform/
```

## Use package notation for Java packages

```
# Good - excludes the entire package
com.myapp.platform.windows

# Also good - using path notation
/com/myapp/platform/windows/
```

## Comment your patterns

```
# Windows-specific UI components (not needed on Mac)
com.myapp.ui.windows

# DirectX native libraries
*.dx11.dll
*.dx12.dll
```

## Testing Platform-Specific Bundles

1. **Build all platform bundles locally** using `jdeploy` package
2. **Compare bundle sizes** to verify exclusions are working
3. **Test installation** on each target platform
4. **Verify functionality** isn't affected by exclusions
